InPouch™ TF (*Tritrichomonas foetus* Bovine)

**PRODUCT BIO**

BioMed Diagnostics’ InPouch™ TF test is a microbiology sample collection, transport, and culture device that allows for simultaneous growth and observation of *Tritrichomonas foetus*, the parasite responsible for the sexually transmitted infection (STI) trichomoniasis in cattle. By combining several procedures into a single device, BioMed’s patented InPouch™ TF test saves time and money, while reducing exposure to collected samples.

The patented InPouch™ system consists of a high barrier, oxygen resistant, plastic pouch with two V-shaped chambers connected by a narrow passage. The innovative two-compartment system allows for direct preliminary observation of a newly collected specimen in the upper chamber, before expressing the contents into the lower chamber for culture and further observation when necessary. Combining both growth and observation into one fully enclosed system removes the need to prepare wet mount slides increasing efficiency and throughput while decreasing the cost of laboratory materials and medical waste.

Additionally, the InPouch™ design lends itself to high performance in off-site or austere environments with limited reliance on laboratory equipment. The InPouch™ TF can be stored for up to a year at room temperature (18-25 °C) and, once inoculated, organisms will be kept viable at this temperature for up to 48 hours before incubation at 37°C is required.

**QUALITY CONTROL**

Quality control testing is performed on each lot of InPouch™ TF prior to shipment in order to ensure viability, doubling time and sterility. Quality control tests are repeated throughout the product shelf life by BioMed Diagnostics confirming the ability of the InPouch™ TF to support the growth of *T. foetus*, while maintaining suppression of commensal microflora.

**BACKGROUND**

Trichomoniasis, commonly known as “trich,” is a veterinary sexually transmitted infection responsible for significant losses in the cattle industry. The causative agent of this venereal disease is a single celled, flagellated protozoan parasite known as *Tritrichomonas foetus*. Bovine trichomoniasis is transmitted to the vagina and uterus of the cow from the prepucial cavity or foreskin of the bull, where the organism resides permanently once a bull is infected. *T. foetus* in cows is characterized by early fetal death as well as various other infections, such as: postcoital pyometra, vaginitis, cervicitis, endometritis, and salpingitis. Bulls, however, are usually asymptomatic. Abortions usually occur early in pregnancy, but can be midterm or late-term and it is unclear how they occur. It is believed that trichomonads infiltrate the amniotic and fluid sac during development. The fetus then ingests the fluid allowing trichomonads to enter areas such as the fetal stomach, intestine, and lungs.
Bulls are usually mature at the time of infection, greater than 3-4 years. Inflammation of the prepuce and glans penis can occur. Trichomonads can be found in the smegma, crypts of the penile shaft, caudal regions as well as the prepuceal cavity of infected bulls.

Economic affects occur primarily due to open cows, repeat breeding, and subsequent longer calving intervals. This affects herds by causing smaller and less uniform calf crops resulting in increased culling rates, demand for replacement females, and veterinary expense.

Infection rates of *T. foetus* in the western United States are higher due to large, free-roaming herds that are allowed to breed freely, however, *T. foetus* infections have become more prevalent in eastern regions as well.

**INPOUCH™ TF DIRECTIONS**

Samples should be taken from scrapings of the bull’s prepuce, or by collecting a sample from the muco-purulent vaginal discharge or uterine discharge of the cow.

To inoculate the upper chamber, tear along the notched area and pull the tabs to open the InPouch™ then introduce the sample. After inoculation, squeeze the top to close and fold the top edge down, roll twice and fold the wire tabs to prevent the InPouch™ from opening. Immediate specimen concentration can be observed under the microscope using the accompanying viewing clip. Only a few viable organisms are needed for detection; an inoculum containing 1 to 10 organisms is sufficient to result in a presumptive positive test.

To culture the InPouch™ TF, express all liquid from the upper chamber into the lower chamber; use the edge of a straight hard surface, such as a workstation or table, for best results. Roll down the pouch until it reaches the top of the lower chamber then fold the wire tabs to lock the InPouch™ into position. Inoculated InPouch™ TF medium can be held up to 48 hours at room temperature (18°-25°C), before incubation at 37°C is required.

Best practice suggests specimens should be examined every 24 hours for six days. The test is considered positive if growth is noted at any time and is considered a presumptive negative after six days without growth.

The medium in this device is compatible with PCR procedures making it a fully functional diagnostic and transportation device.

**DETECTION**

As the parasites multiply, white sediment along the sides and bottom of the chamber will become visible. Five flagella arise from the organism, four immediately extend out, while the fifth wraps backwards along the surface of the organism and a barb-like axostyle projection can be seen across from the four-flagella bundle. If *T. foetus* organisms are present, they will be identifiable by their distinct features; characteristically the rolling, jerky motions exhibited by the protozoan, which can be seen using a 10X objective lens.
